Variability in Capsaicinoids content and phylogenetic analysis of AT3, an Acyltransferase gene in Chilli (Capsicum annuum L.)

P Naresh, K Madhavi Reddy, M Krishna Reddy and KV Ravishankar

Received : October, 2011 / Accepted : February, 2012

Abstract : Capsaicinoids are the alkaloids responsible for pungency in chilli fruits. Estimates of capsaicinoids obtained by colorimetric method and HPLC were highly correlated ($R^2 = 0.996$). Data suggest that colorimetric method an effective means for estimating total capsaicinoids in extracts of fresh chilli fruits. Thirty accesions were screened using colorimetric method and considerable variability was observed for total capsaicinoids (0-1.65 %). In order to see sequence polymorphism associated with pungency level, we cloned and sequenced part of AT3 gene, an acyltransferase belonging to the BAHD family of acyltransferases. Results revealed that abundant indel (insertion and deletion events) and SNP (single nucleotide polymorphisms) in the cloned AT3 partial sequence. Both AT3-1 and AT3-2 are present in many cultivars that suggest paralogous gene lineages.

Introduction

Pungency (heat) is an important quality attribute of hot pepper besides colour (carotenoids). The nature of pungency has been established as a mixture of seven or more homologous braded-chain alkyl vanillylamides, named capsaicinoids (Torabi, 1997). Capsaicinoids are unique to the genus *Capsicum* and is produced in glands on the placenta of the fruit, they are odourless, colourless, flavourless, non-nutrient compounds. Capsaicin, a major alkaloid among capsaicinoids has wide applications in the food, medicine and pharmaceutical industries. As a medicine, capsaicin is known to kill some types of cancer cells (Min *et al.*, 2004) and provide relief in arthritis and respiratory ailments (Mazzone and Geraghty, 1999). Chillies have been included in ayurvedic medicines and used as tonic toward off many diseases. The pharmaceutical application of capsaicinoids is attributed to its antioxidant, anticancer, antiarthritic and analgesic properties (Prasad *et al.*, 2006). Pungency in chilli is measured by Scoville scale which was named after Wilbur Scoville. One of the hottest chillies "Naga or Bhut Jolokia" (8, 55, 000 SHU) in the world is found in Tezpur India.

A single locus C has been reported to be essential for the control of production of capsacinoids, the pungent allele is dominant over the non-pungent allele (Ben chaim et al., 2001; Blum et al., 2002). Lang et al. (2006) isolated two genes characterized as putative Capsicum acyltransferase (Catf-1 and Catf-2) from placenta of pungent pepper, expression of *catf-1* coincided with accumulation of capsaicinods suggesting that *catf-1* is a candidate gene differentiating pungent and non-pungent peppers. Through candidate gene analysis, Stellari et al. (2009) identified that the mutation results in the loss of pungency is a deletion in the gene AT-3 (encodes an acyltransferase protein) which belongs to BAHD family. Fruit quality breeding is a major challenge to hot/ bell pepper breeders and to speed up the breeding process, molecular markers associated with quality traits in chilli could be effectively used to rapidly screen a large number of individual plants. With this objective, nucleotide variation at AT3 (a candidate gene underlying the Pun1 locus) was studied to identify the possible sequence polymorphisms that could be associated with pungency level that can be used for development of molecular marker for pungency.

Materials and methods

Thirty pepper accessions with varied pungency level were selected from germplasm accessions for analysis of total capsaicinoids (Table 1). The plants were grown in field during 2009 *kharif* season (eastern dry zone of Karnataka state, at 12° 58′ north latitude, 77° 45′ east longitude and at an altitude of 930 meters above the mean sea level and average rainfall of this area is about 800mm)

P Naresh, K Madhavi Reddy, MK Reddy and KV Ravishankar Division of Vegetable Crops, Indian Institute of Horticultural Research, Hessaraghatta Lake Post, Bangalore-560089, Karnataka, India

and all standard cultivation practices recommended for the locality were practiced. Fruit samples were harvested at full ripe stage and were dried in the oven at 60° C for 36 h, ground in an electronic grinder, and passed through a 0.5mm sieve. Total capsaicinoids content of chilli lines (Table 2) was determined using colorimetric method as described by Bajaj *et al.*, (1980) and representative seven chilli lines was also determined using HPLC method (Suzuki, 1984) to compare sensitivity of colorometric method.

Colorimetric method: 0.5g dry chilli powder was weighed 10ml dry acetone was added into the glass stoppered test tube and kept overnight for extraction. Next day samples were centrifuged at 10000rpm for 10min and 1ml of the clear supernatant was taken into a test tube and evaporated to dryness in a hot water bath. The residue was dissolved in 5ml of 0.4% of NaOH solution and 3ml of 3% phosphomolybdic acid was added. The contents were shaken and left undisturbed for 1hr. After 1hr the solution was quickly transferred into centrifuge tubes to remove any floating debris, and then centrifuged at 5000rpm for 15min. The clear blue coloured solution was directly transferred into the cuvette and absorbance was read at 650nm along with a reagent blank. A standard graph was prepared using 0-200 µg pure capsaicin. Simultaneously 0.2, 0.4, 0.6, 0.8 and 1ml of working standard solution were taken into new test tubes and proceeded as mentioned above. Percent capsaicin calculated using the formula mentioned below;

% capsaicin = $\mu g \text{ capsaicin X 100 X 100} \\ 1000 \text{ X 1000 X 1 X 0.5}$

Percent capsaicin values were converted to SHU (Scoville Heat Units) multiplying the pepper dry weight concentrations by the coefficients of heat value 1,60,00,000 for capsaicin (Govindarajan *et al.*, 1977).

HPLC method: Two grams of dried powder was weighed and boiled with 95% ethanol for 30min for extraction; the final extract was made up to 50ml. The mixtures were filtered with filter paper, and then with a syringe driven filter (RanDisc Nylon 0.22μm). A 20μl aliquot of flow through solution (capsaicinoid extract) was analyzed by high performance liquid chromatography (HPLC) using a GEMINI 5μm C18 110A column (100mm (L) x 1.0mm (D) (Phenomenex Chemicals) with a mobile phase of 40% acetonitrile and 60% distilled water at a flow rate of 1.0ml/ min at 28°C. The UV absorbance at 205nm was measured. The peak areas were converted to mg based on the standards.

Primers designing and PCR amplification: Genomic DNA was extracted from young leaves using CTAB method. The available gene sequences of Capsicum acyltransferase (AT3-2) were retrieved from the public databases, NCBI, multiple alignments of sequences has been done using CLUSTAL-W software, conserved regions were selected and based on which forward and reverse primers (Catf-F aaggacttgccttgggcgaa, Catf-R ctgtgttgcacatttgaaaaga) were designed manually to amplify 840bp of AT3-2. PCR analysis were performed in 25 µl reaction volumes containing 2.5µl of 10X PCR buffer, 1 unit Pfu Taq DNA polymerase, 3µl of 1mM dNTPs, 2.5µl of 5µM forward primer, 2.5µl of 5 µM reverse primer, 11.25µl of dH2O, and 3µl of 20ng/µl DNA template. The PCR profile comprised initial denaturation of 4 min at 95°C, followed by 35 cycles of 94°C for 1 min, 64°C for 1 min, 72°C for 1 min and final extension of 5 min at 72°C. PCR products were separated on 2% agarose gel.

Cloning and sequencing: For sequence analysis, Bhut Jolokia (8,55,000 SHU), Habanero (3,00,000 SHU), EC631844 (1,60,000 SHU), PBC495 (1,10,000 SHU), PBC521 (1,15,000 SHU), PantC-1 (90,000 SHU), LCA 334 (95,000 SHU), Kashi Anmol (45,000 SHU), Arka Abhir (20,000 SHU), Arka Mohini (0 SHU) and PBC 1022 (0 SHU) were selected and amplified products were cloned. The DNA fragment were recovered using gel extraction kit (Cat# 28704, QIAGEN, GmbH, Hilden, Germany). The PCR amplified DNA fragment was cloned into the plasmid vector pTZ57R/T using InsT/A clone PCR Product cloning kit (Cat#K1214, MBI, Fermentas) following the manufacturer's instruction. The T/A cloning method is suitable for cloning of PCR fragments amplified with primers that carry dG or dC at their 5' ends. Ligation was carried out at 22°C for 16 hrs. The ligation mixture was used for transformation. Plasmids were isolated from positive clone cultures and the plasmids were sent for sequencing (Eurofins Biotechnologies Pvt. Ltd. USA) and were sequenced in both directions with respective primers using ABI3700 DNA analyzer (Applied Biosystems, USA).

SNP identification and analysis: The contigs for each genotype were generated using both forward and reverse sequence chromatograms with the help of Bioedit programme. The contig sequences were subjected to BLAST in the NCBI website. Later, these sequences were used to develop multiple sequence alignment (MSA) using online ClustalW programme (http://www.ebi.ac.uk/tools/ clustalw2/index.html). The MSA files were used to analyze the presence of SNP specific to genotype.

Results and Discussion

Variability of total capsaicinoids in Capsicum accessions

Estimates of capsaicinoids obtained by colorimetric method and HPLC were highly correlated ($R^2 = 0.996$) (Table 1 and Fig. 1). The colorometric method using phosphomolybdic acid reagent showed consistent results, which is cheap, easy and can be effectively used for screening large samples. Bhut Jolokia and Habenaro fruits were not analyzed due to insufficient sample size. As expected there is considerable variability for levels of total capsacinoids (Table 1) ranged from 0% (Arka Mohini and PBC1022) to 1.65% (EC631817, a small fruited line of *Capsicum chinense*). Similar high variation was reported by Bajaj et al. (1980), Anu and Peter (2000), Sathiyamurthy et al., (2001), Singh et al. (2003), Kaur and Singh (2008) and Thul et al. (2009). Further the pungent lines identified in this study can be used in breeding for high nutraceutical value.

Allelic variation at AT3 gene

The 5' 3' primers amplified a single, specific band of 840bp size in all the lines without showing any polymorphism on agarose gel between pungent and nonpungent genotypes. EC631817 (C. chinense) and PBC 80 (C. baccatum) did not get amplified. Interestingly only ornamental chilli (a wild species) showed 700 bp amplified product, which is a non-pungent (sweet). The gel picture showing the amplification was presented in Fig.1. PCR amplified products of the selected 12 genotypes with varied level of pungency were cloned and sequenced. The sequences showed maximum similarity (99%) to AT3-2 gene, when the sequences were subjected to BLAST at NCBI but ornamental chilli (wild species) shown similarity to AT3-1. Further, already available nucleotide sequences for AT3 gene in public domain were also composed. Multiple alignments of the nucleotide sequences were performed and the presence of structural changes in the sequences was found. Several SNPs were found scattered throughout the cloned sequence (Table 3). Stellari et al. (2009) also reported that Pun1 alleles of C. annuum, C. chinense and C. frutescens differed by single nucleotide

M-100bp ladder

Fig 1: Gel profile of *Acyltransferase* gene specific primers in 30 chilli accessions with varied level of pungency

polymorphisms scattered throughout the gene and each mutation has an independent origin predating the diversification of the species complex. Bhut Jolokia showed 99% similarity to the Habanero cultivar in the sequenced 840bp except for a single nucleotide change at 769 bp *i.e.* instead of guanine (G), thiamine (T) was present, indicating that Bhut Jolokia and Habanero are derived from *C.chinense*.

Neighbour-Joining phylogenetic tree constructed from the ClustalW alignment of the partial nucleotide sequences of AT3 gene (Fig. 2) showed three major clusters; Ornamental chilli (a wild species) getting into completely different cluster i.e. cluster I. Cluster II included Capsicum rhomboideum (GenBank acc. No. FJ755165) in which recombination has occurred between AT3-1 and AT3-2 (Stellari et al., 2009), cluster III contained *Pun1* alleles. The *Pun1* locus was the only locus identified that had a qualitative effect on pungency (Blum et al., 2002). Two sub-clusters were found in cluster III i.e cluster III A included AT3-1 sequences and cluster III B included AT3-2 sequences of different lines and showed clear demarcation of AT3-1 from AT3-2 (Pun 1 encodes AT3, an acyltransferase belonging to the BAHD family of acyltransferases. A tandem duplication of this gene, designated as AT3-1 and AT3-2, respectively). Phylogenetic analysis demonstrated that the paralogous gene lineages of AT3-1 and AT3-2 from well supported phylogenetic clades (Stellari et al., 2009). Further, non pungent alleles are scattered and not clustered together into a single clade suggesting multiple origins of the loss of pungency. This result sheds light on AT3-2, as only part of the gene sequence was studied further characterization of full length sequence and understanding the AT3-2 will undoubtedly provide a valuable resource for marker-assisted selection and
